

## Syntax

We will adopt the following meta-variable conventions:

$x \in \text{Var}$	variables
$b \in \{\mathbf{true}, \mathbf{false}\}$	booleans
$n \in \mathbb{Z}$	integers
$s \in \Sigma^*$	ASCII strings
$\ell \in \text{Loc}$	memory locations
$h \in \text{Hand}$	process handles
$\rho \in \text{Prom}$	promises

The abstract syntax of **expressions** can be defined as follows, using auxiliary definitions for patterns  $p$ , unary operations  $\odot$ , binary operations  $\oplus$ , and types  $\tau$  given below:

$e \in \text{Exp} ::=$	$()$	<i>Unit</i>
	$b$	<i>Booleans</i>
	$n$	<i>Integers</i>
	$s$	<i>Strings</i>
	$x$	<i>Variables</i>
	$(e_1, e_2)$	<i>Pairs</i>
	$[]$	<i>Empty list</i>
	$e_1 :: e_2$	<i>Non-empty lists</i>
	$\mathbf{fun} (p : \tau) \rightarrow e$	<i>Functions</i>
	$\mathbf{let} (p : \tau) = e_1 \mathbf{in} e_2$	<i>Let definitions</i>
	$\mathbf{let} \mathbf{rec} (f : \tau_1) = \mathbf{fun} (p : \tau_2) \rightarrow e_1 \mathbf{in} e_2$	<i>Recursive function definitions</i>
	$e_1 e_2$	<i>Function application</i>
	$\odot e$	<i>Unary operators</i>
	$e_1 \oplus e_2$	<i>Binary operators</i>
	$e_1; e_2$	<i>Sequence</i>
	$\mathbf{if} e_1 \mathbf{then} e_2 \mathbf{else} e_3$	<i>Conditionals</i>
	$\mathbf{match} e_0 \mathbf{with} \mid p_1 \rightarrow e_1 \dots \mid p_n \rightarrow e_n \mathbf{end}$	<i>Pattern matching</i>
	$\mathbf{ref} e$	<i>Reference creation</i>
	$!e$	<i>Dereference</i>
	$e_1 := e_2$	<i>Assignment</i>
	$\mathbf{return} e$	<i>Asynchronous return</i>
	$\mathbf{await} (p : \tau) = e_1 \mathbf{in} e_2$	<i>Asynchronous bind</i>
	$e_1 >>= e_2$	<i>Asynchronous bind - infix</i>
	$\mathbf{send} e_1 \mathbf{to} e_2$	<i>Asynchronous message send</i>
	$\mathbf{recv} e$	<i>Asynchronous message receive</i>
	$\mathbf{spawn} e_1 \mathbf{with} e_2$	<i>Asynchronous spawn</i>
	$\mathbf{self}$	<i>Self handle literal</i>

The syntax for patterns, unary operations, and binary operations is defined as follows:

$p \in \text{Pat} ::=$	$\_ \mid x \mid () \mid b \mid n \mid s \mid (p_1, p_2) \mid [] \mid p_1 :: p_2$
$\odot \in \text{UOp} ::=$	$- \mid \mathbf{not}$
$\oplus \in \text{BOp} ::=$	$+ \mid - \mid * \mid / \mid \% \mid \&\& \mid    \mid < \mid <= \mid > \mid >= \mid = \mid <> \mid ^ \mid  >$

The set of **types** is defined as follows:

$\tau \in \text{Type} ::=$	<b>unit</b>	<i>Unit Type</i>
	<b>bool</b>	<i>Boolean Type</i>
	<b>int</b>	<i>Integer Type</i>
	<b>string</b>	<i>String Type</i>
	$\tau_1 * \tau_2$	<i>Pair Types</i>
	$\tau \text{ list}$	<i>List Types</i>
	$\tau_1 \rightarrow \tau_2$	<i>Function Types</i>
	$\tau \text{ ref}$	<i>Reference Types</i>
	$\tau \text{ promise}$	<i>Promise Types</i>
	<b>handle</b>	<i>Handle Types</i>
	$\alpha$	<i>Type Variables</i>
	$\forall(\tau_1 \rightarrow \tau_2)$	<i>Polymorphic Type</i>

The set of **values** is defined as follows, using the auxiliary definition for environments  $\mathcal{E}$ , which is given below:

$v \in \text{Val} ::=$	<b>()</b>	<i>Unit</i>
	<b>b</b>	<i>Boolean</i>
	<b>n</b>	<i>Integers</i>
	<b>s</b>	<i>Strings</i>
	<b>(v<sub>1</sub>, v<sub>2</sub>)</b>	<i>Pairs</i>
	<b>[]</b>	<i>Empty list</i>
	<b>v<sub>1</sub> :: v<sub>2</sub></b>	<i>Non-empty lists</i>
	<b>(<math>\mathcal{E}, p, e</math>)</b>	<i>Closures</i>
	<b>ℓ</b>	<i>Locations</i>
	<b>ρ</b>	<i>Promises</i>
	<b>h</b>	<i>Handles</i>

**Environments** and **stores** are defined as partial functions from variables to values and from locations to values respectively:

$$\begin{aligned} \mathcal{E} &\in \text{Var} \rightarrow \text{Val} \\ \sigma &\in \text{Loc} \rightarrow \text{Val} \end{aligned}$$

We use the following notation for describing environments:

- $\text{dom } \mathcal{E}$  denotes the domain of  $\mathcal{E}$ , that is the set of variables that it is defined on,
- $\{\}$  denotes the environment that is undefined on all variables,
- $\{x \mapsto v\}$  denotes the environment that maps  $x$  to  $v$  and is otherwise undefined,
- $\mathcal{E}_1 \circ \mathcal{E}_2$  denotes the environment that maps  $x$  in  $\text{dom } \mathcal{E}_2$  to  $\mathcal{E}_2(x)$ ,  $x$  in  $\text{dom } \mathcal{E}_1$  but not in  $\text{dom } \mathcal{E}_2$  to  $\mathcal{E}_1(x)$ , and is otherwise undefined.

We use the same notation for the analogous operations on stores  $\sigma$ .

## Concurrency Library

To simplify the task of specifying and implementing RML, we will assume the existence of an **Lwt**-like concurrency library that provides a set of basic primitives that can be used to implement the concurrent operations in RML. We let  $\Delta \in \text{State}$  range over the run-time state of this library and assume the following operations:

$$\begin{aligned}
\text{return} &\in \text{State} \rightarrow \text{Val} \rightarrow \text{State} \times \text{Prom} \\
\text{bind} &\in \text{State} \rightarrow \text{Prom} \rightarrow (\text{State} \times \text{Store} \times \text{Val} \rightarrow \text{State} \times \text{Store} \times \text{Prom}) \rightarrow \text{State} \times \text{Prom} \\
\text{send} &\in \text{State} \rightarrow \text{Hand} \rightarrow \text{Val} \rightarrow \text{State} \times \{()\} \\
\text{recv} &\in \text{State} \rightarrow \text{Hand} \rightarrow \text{State} \times \text{Prom} \\
\text{spawn} &\in \text{State} \rightarrow \text{Val} \rightarrow \text{Val} \rightarrow \text{State} \times \text{Hand} \\
\text{self} &\in \text{Env} \rightarrow \text{Hand}
\end{aligned}$$

## Semantics

The semantics of an RML program can be obtained by modeling the behavior of the concurrency library. Intuitively, the run-time state  $\Delta$  can be thought of as encoding multiple threads of execution, each with its own thread-local environment, store, and expression, and a single step  $\Delta \rightarrow \Delta'$  models the sequential execution of a single thread until it relinquishes control back to the library. The overall behavior emerges by non-deterministically interleaving the steps for individual threads.

In this assignment, to keep things simple, we will not actually model this top-level operational semantics. Instead, we will formalize the evaluation of individual threads using a big-step semantics. Formally, we will define a relation,

$$\langle \Delta, \sigma, \mathcal{E}, e \rangle \Downarrow \langle \Delta', \sigma', v \rangle$$

which can intuitively be read as follows: “under run-time state  $\Delta$ , with store  $\sigma$ , and environment  $\mathcal{E}$ , the expression  $e$  evaluates to run-time state  $\Delta'$ , store  $\sigma'$ , and value  $v$ .” Note that each big step does not necessarily fully evaluate  $e$ , but merely models its execution up until the next program point where it relinquishes control back to the concurrency library.

To define the big-step evaluation relation, we will use **inference rules**:

$$\text{E-SEQUENCE} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, () \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}{\langle \Delta, \sigma, \mathcal{E}, e_1; e_2 \rangle \Downarrow \langle \Delta', \sigma, v \rangle}$$

Such rules are similar to the definitions we have seen in lecture, and can be read from bottom to top. The **conclusion** below the line, such as  $\langle \Delta, \sigma, \mathcal{E}, e \rangle \Downarrow \langle \Delta', \sigma, v \rangle$ , holds if all of the **premises** above the line, such as  $\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, () \rangle$  and  $\langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle$ , also hold. Note that any variables in the terms above the line, such as  $\Delta_1$  and  $\sigma_1$  may be filled in with arbitrary values, provided all of the constraints encoded in the premises are satisfied.

## Simple Expressions

To warm up, let us consider the semantics of several simple expressions: values, pairs, lists, and variables.

$$\begin{array}{c}
\text{E-VALUE} \frac{}{\langle \Delta, \sigma, \mathcal{E}, v \rangle \Downarrow \langle \Delta, \sigma, v \rangle} \qquad \text{E-VAR} \frac{\mathcal{E}(x) = v}{\langle \Delta, \sigma, \mathcal{E}, x \rangle \Downarrow \langle \Delta, \sigma, v \rangle} \\
\\
\text{E-PAIR} \frac{\frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, v_1 \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma', v_2 \rangle}{\langle \Delta, \sigma, \mathcal{E}, (e_1, e_2) \rangle \Downarrow \langle \Delta', \sigma', (v_1, v_2) \rangle}}{} \\
\\
\text{E-CONS} \frac{\frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, v_1 \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma', v_2 \rangle}{\langle \Delta, \sigma, \mathcal{E}, e_1 :: e_2 \rangle \Downarrow \langle \Delta', \sigma', v_1 :: v_2 \rangle}}{}
\end{array}$$

Intuitively, these inference rules can be understood as follows:

**E-VALUE:** a value  $v$  evaluates to itself, as in most big-step semantics. The run-time state  $\Delta$  and store  $\sigma$  are unchanged.

**E-VAR:** a variable  $x$  evaluates to the value obtained by looking up  $x$  in the environment  $\mathcal{E}$ . Again, the run-time state  $\Delta$  and store  $\sigma$  are unchanged.

**E-PAIR:** a pair expression  $(e_1, e_2)$  evaluates to a pair value  $(v_1, v_2)$  in the obvious way. Note that the effects on the run-time state  $\Delta$  and store  $\sigma$  are accumulated from left to right.

**E-CONS:** a cons expression  $e_1 :: e_2$  evaluates to a non-empty list value  $v_1 :: v_2$  in the obvious way.

## Pattern Matching Expressions

To model pattern matching, we will use a three-place relation of the form  $v : p \rightsquigarrow \mathcal{E}$ , read as “value  $v$  matches pattern  $p$  and produces the bindings in  $\mathcal{E}$ .”

$$\begin{array}{c}
\frac{}{v : \_ \rightsquigarrow \{ \}} \text{M-WILD} \qquad \frac{}{v : x \rightsquigarrow \{ x \mapsto v \}} \text{M-VAR} \qquad \frac{}{() : () \rightsquigarrow \{ \}} \text{M-UNIT} \\
\\
\frac{}{b : b \rightsquigarrow \{ \}} \text{M-BOOL} \qquad \frac{}{n : n \rightsquigarrow \{ \}} \text{M-INT} \qquad \frac{}{s : s \rightsquigarrow \{ \}} \text{M-STRING} \\
\\
\frac{}{[] : [] \rightsquigarrow \{ \}} \text{M-EMPTYLIST} \qquad \frac{v_1 : p_1 \rightsquigarrow \mathcal{E}_1 \quad v_2 : p_2 \rightsquigarrow \mathcal{E}_2}{(v_1, v_2) : (p_1, p_2) \rightsquigarrow \mathcal{E}_1 \circ \mathcal{E}_2} \text{M-PAIR} \\
\\
\frac{v_1 : p_1 \rightsquigarrow \mathcal{E}_1 \quad v_2 : p_2 \rightsquigarrow \mathcal{E}_2}{v_1 :: v_2 : p_1 :: p_2 \rightsquigarrow \mathcal{E}_1 \circ \mathcal{E}_2} \text{M-CONS}
\end{array}$$

Each of these rules are straightforward, recursing on the value and pattern in lock-step, and collecting up bindings in an environment.

The inference rule for pattern matching is as follows.

$$\text{E-MATCH} \frac{\begin{array}{c} \langle \Delta, \sigma, \mathcal{E}, e \rangle \Downarrow \langle \Delta_e, \sigma_e, v \rangle \quad v : p_j \rightsquigarrow \mathcal{E}_j \text{ for } 0 < j < n + 1 \\ \langle \Delta_e, \sigma_e, \mathcal{E} \circ \mathcal{E}_j, e_j \rangle \Downarrow \langle \Delta', \sigma', v \rangle \quad v : p_i \not\rightsquigarrow \mathcal{E}_i \text{ for } i < j \end{array}}{\langle \Delta, \sigma, \mathcal{E}, \text{match } e \text{ with } | p_1 \rightarrow e_1 \ \dots \ | p_n \rightarrow e_n \text{ end} \rangle \Downarrow \langle \Delta', \sigma', v \rangle}$$

This inference rule evaluates  $e$  to a value  $v$ , finds the first pattern  $p_j$  that matches  $v$ , and then evaluates the corresponding expression  $e_j$  in an environment extended with the bindings from  $v$  obtained using  $p_j$ .

## Functions, Definitions, and Application Expressions

The next few inference rules handle functions, **let**-definitions, and application expressions.

$$\begin{array}{c} \text{E-FUN} \frac{}{\langle \Delta, \sigma, \mathcal{E}, \text{fun } (p : \tau) \rightarrow e \rangle \Downarrow \langle \Delta, \sigma, \langle \mathcal{E}, p, e \rangle \rangle} \\ \\ \text{E-APP} \frac{\begin{array}{c} \langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, \langle \mathcal{E}_{cl}, p_{cl}, e_{cl} \rangle \rangle \\ \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta_2, \sigma_2, v_2 \rangle \quad v_2 : p_{cl} \rightsquigarrow \mathcal{E}_2 \\ \langle \Delta_2, \sigma_2, \mathcal{E}_{cl} \circ \mathcal{E}_2, e_{cl} \rangle \Downarrow \langle \Delta', \sigma', v \rangle \end{array}}{\langle \Delta, \sigma, \mathcal{E}, e_1 \ e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle} \\ \\ \text{E-PIPE} \frac{\langle \Delta, \sigma, \mathcal{E}, e_2 \ e_1 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}{\langle \Delta, \sigma, \mathcal{E}, e_1 \ |> e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle} \\ \\ \text{E-LET} \frac{\begin{array}{c} \langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, v_1 \rangle \\ v_1 : p \rightsquigarrow \mathcal{E}_1 \quad \langle \Delta_1, \sigma_1, \mathcal{E} \circ \mathcal{E}_1, e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle \end{array}}{\langle \Delta, \sigma, \mathcal{E}, \text{let } (p : \tau) = e_1 \text{ in } e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle} \\ \\ \text{E-LETREC} \frac{\mathcal{E}_f = \mathcal{E}[f \mapsto \langle \mathcal{E}_f, p, e_1 \rangle] \quad \langle \Delta, \sigma, \mathcal{E}_f, e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}{\langle \Delta, \sigma, \mathcal{E}, \text{let rec } (f : \tau_1) = \text{fun } (p : \tau_2) \rightarrow e_1 \text{ in } e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}$$

These inference rules can be understood as follows:

**E-FUN:** a function **fun**  $p \rightarrow e$  evaluates to a closure

**E-APP:** an application  $e_1 \ e_2$  evaluates  $e_1$  to a closure  $\langle \mathcal{E}, p, e \rangle$ , evaluates  $e_2$  to a value  $v_2$ , matches  $v_2$  against the pattern  $p$ , and finally evaluates the body of the closure  $e$ .

**E-PIPE:** an application of the binary operator  $e_1 \ |> e_2$  de-sugars to the application  $e_1 \ e_2$ .

**E-LET:** a **let**-definition evaluates the first expression  $e_1$  to a value  $v_1$ , and then evaluates the second expression  $e_2$  in an environment in which variables bound in  $p$  are mapped to the corresponding values in  $v_1$ .

**E-LETREC:** is similar to the case for **let**-definitions. It builds a recursive environment  $\mathcal{E}_f$  in which  $f$  is bound to the closure for the function with parameter  $p$  and body  $e_1$ , and then uses this environment to evaluate the second expression  $e_2$ .

## Unary and Binary Operations

The next few rules model unary and binary operations.

$$\begin{array}{c} \text{E-UOP} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta', \sigma', v_1 \rangle \quad v = \llbracket \odot \rrbracket v_1}{\langle \Delta, \sigma, \mathcal{E}, \odot e_1 \rangle \Downarrow \langle \Delta', \sigma', v \rangle} \\[2ex] \text{E-BOP} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, v_1 \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma', v_2 \rangle \quad v = \llbracket \oplus \rrbracket v_1 v_2}{\langle \Delta, \sigma, \mathcal{E}, e_1 \oplus e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle} \end{array}$$

These inference rules can be understood as follows:

**E-UOP:** a unary operation  $\odot e_1$  evaluates  $e_1$  to a value  $v_1$  and then uses the implementation of the operation, denoted  $\llbracket \odot \rrbracket$ , to produce the final value  $v$ . Note that implementations may require the value  $v_1$  to have a specific type—e.g., unary negation is only defined on integers.

**E-BOP:** similar to the case for unary operations. Note that this inference rule is not quite correct in the case of boolean operators with short-circuit semantics, which may not necessarily evaluate  $e_2$ . We leave the task of formalizing the correct semantics as an exercise. We also implicitly require that the values  $v_1$  and  $v_2$  are of the expected type for the operation  $\oplus$ ; for instance, if the addition is addition, then  $v_1$  and  $v_2$  must be integer values (and not, say, booleans or strings). The equality ( $=$ ) and inequality ( $<>$ ) operators are only defined when the two sides have the same, *base* type: **bool**, **int**, or **string**.

## Standard Control-Flow Expressions

The next few rules model standard control-flow expressions.

$$\text{E-SEQUENCE} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, () \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}{\langle \Delta, \sigma, \mathcal{E}, e_1; e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}$$

$$\begin{array}{c}
\text{E-IF-TRUE} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, \mathbf{true} \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}{\langle \Delta, \sigma, \mathcal{E}, \mathbf{if } e_1 \mathbf{ then } e_2 \mathbf{ else } e_3 \rangle \Downarrow \langle \Delta', \sigma', v \rangle} \\
\\
\text{E-IF-FALSE} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, \mathbf{false} \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_3 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}{\langle \Delta, \sigma, \mathcal{E}, \mathbf{if } e_1 \mathbf{ then } e_2 \mathbf{ else } e_3 \rangle \Downarrow \langle \Delta', \sigma', v \rangle}
\end{array}$$

These inference rules can be understood as follows:

**E-SEQUENCE:** a sequential composition  $e_1; e_2$  evaluates  $e_1$  to unit  $()$  and then evaluates  $e_2$  to a value  $v$ .

**E-IF-TRUE and E-IF-FALSE** a conditional **if**  $e_1$  **then**  $e_2$  **else**  $e_3$  first evaluates  $e_1$  to a boolean, and then either evaluates  $e_2$  or  $e_3$ . Note however that it does *not* evaluate both  $e_2$  and  $e_3$ .

## Imperative Expressions

The next few inference rules model OCaml-style references:

$$\begin{array}{c}
\text{E-REF} \frac{\langle \Delta, \sigma, \mathcal{E}, e \rangle \Downarrow \langle \Delta', \sigma_e, v \rangle \quad \ell \notin \text{dom } \sigma \quad \sigma' = \sigma_e \circ \{\ell \mapsto v\}}{\langle \Delta, \sigma, \mathcal{E}, \mathbf{ref } e \rangle \Downarrow \langle \Delta', \sigma', \ell \rangle} \\
\\
\text{E-DEREF} \frac{\langle \Delta, \sigma, \mathcal{E}, e \rangle \Downarrow \langle \Delta', \sigma', \ell \rangle \quad v = \sigma(\ell)}{\langle \Delta, \sigma, \mathcal{E}, !e \rangle \Downarrow \langle \Delta', \sigma', v \rangle} \\
\\
\text{E-ASSIGN} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, \ell \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta', \sigma_2, v \rangle \quad \sigma' = \sigma_2 \circ \{\ell \mapsto v\}}{\langle \Delta, \sigma, \mathcal{E}, e_1 := e_2 \rangle \Downarrow \langle \Delta', \sigma', () \rangle}
\end{array}$$

These inference rules can be understood as follows:

**E-REF:** a reference **ref**  $e$  evaluates  $e$  to a value  $v$  and then adds it to the store  $\sigma$  under a fresh location  $\ell$ , which is returned as the result.

**E-DEREF:** a dereference  $!e_1$  evaluates  $e_1$  to a location  $\ell$  and then looks it up in the store  $\sigma$ .

**E-ASSIGN:** an assignment  $e_1 := e_2$  evaluates  $e_1$  to a location  $\ell$  and  $e_2$  to a value, updates the store  $\sigma$  so that  $\ell$  maps to  $v_2$ , and returns  $()$ .

## Asynchronous Expressions

The final inference rules model asynchronous expressions. Most of these rules simply call out to the corresponding functions from the concurrency library.

$$\begin{array}{c}
\text{E-RETURN} \frac{\langle \Delta, \sigma, \mathcal{E}, e \rangle \Downarrow \langle \Delta_e, \sigma', v \rangle \quad \Delta', \rho = \text{return } \Delta_e v_1}{\langle \Delta, \sigma, \mathcal{E}, \text{return } e \rangle \Downarrow \langle \Delta', \sigma', \rho \rangle} \\
\\
\text{E-AWAIT} \frac{\Delta', \rho = \text{bind } \Delta_1 \rho_1 (\lambda(\Delta'', \sigma'', v''). \rho_2 \text{ where } v'' : p \rightsquigarrow \mathcal{E}'' \text{ and } \langle \Delta'', \sigma'', \mathcal{E} \circ \mathcal{E}'', e_2 \rangle \Downarrow \langle \Delta_2, \sigma_2, \rho_2 \rangle) \quad \langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma', \rho_1 \rangle}{\langle \Delta, \sigma, \mathcal{E}, \text{await } (p : \tau) = e_1 \text{ in } e_2 \rangle \Downarrow \langle \Delta', \sigma', \rho \rangle} \\
\\
\text{E-BIND} \frac{\Delta', \rho = \text{bind } \Delta_2 \rho_1 (\lambda(\Delta'', \sigma'', v''). \rho_2 \text{ where } v'' : p \rightsquigarrow \mathcal{E}'' \text{ and } \langle \Delta'', \sigma'', \mathcal{E}_{cl} \circ \mathcal{E}'', e_{cl} \rangle \Downarrow \langle \Delta', \sigma', \rho_2 \rangle) \quad \langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, \rho_1 \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta_2, \sigma_2, (|\mathcal{E}_{cl}, p, e_{cl}|) \rangle}{\langle \Delta, \sigma, \mathcal{E}, e_1 >>= e_2 \rangle \Downarrow \langle \Delta', \sigma_2, \rho \rangle} \\
\\
\text{E-SEND} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, v_1 \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta_2, \sigma', h_2 \rangle \quad \Delta', () = \text{send } \Delta_2 v_2 h_2}{\langle \Delta, \sigma, \mathcal{E}, \text{send } e_1 \text{ to } e_2 \rangle \Downarrow \langle \Delta', \sigma', () \rangle} \\
\\
\text{E-RECV} \frac{\langle \Delta, \sigma, \mathcal{E}, e \rangle \Downarrow \langle \Delta_e, \sigma_e, h \rangle \quad \Delta', \rho = \text{recv } \Delta_e h}{\langle \Delta, \sigma, \mathcal{E}, \text{recv } e \rangle \Downarrow \langle \Delta', \sigma', \rho \rangle} \\
\\
\text{E-SPAWN} \frac{\langle \Delta, \sigma, \mathcal{E}, e_1 \rangle \Downarrow \langle \Delta_1, \sigma_1, v_1 \rangle \quad \langle \Delta_1, \sigma_1, \mathcal{E}, e_2 \rangle \Downarrow \langle \Delta_2, \sigma', v_2 \rangle \quad \Delta', h = \text{spawn } \Delta_2 v_1 v_2}{\langle \Delta, \sigma, \mathcal{E}, \text{spawn } e_1 \text{ with } e_2 \rangle \Downarrow \langle \Delta', \sigma', h \rangle} \\
\\
\text{E-SELF} \frac{h = \text{self } \mathcal{E}}{\langle \Delta, \sigma, \mathcal{E}, \text{self} \rangle \Downarrow \langle \Delta, \sigma, h \rangle}
\end{array}$$

These inference rules can be understood as follows:

- E-RETURN:** a return expression **return**  $e$  evaluates  $e$  to a value  $v$  and uses the library function *return* to obtain a promise  $\rho$ .
- E-AWAIT:** an await expression **await**  $p = e_1$  **in**  $e_2$  evaluates  $e_1$  to a promise  $\rho$  and then schedules a call-back with parameters  $p$  and body  $e_2$  that is executed when  $\rho$  is resolved. The notation  $\lambda v. v'$  used to describe the call-back function denotes the function that takes a parameter  $v$  and yields a result  $v'$ .
- E-BIND:** an application of the binary operator  $e_1 >>= e_2$  evaluates  $e_1$  to a promise  $\rho$  and  $e_2$  to a function closure  $(|\mathcal{E}, p, e|)$  and then schedule a call-back with parameters  $p$  and body  $e$  that is executed when  $\rho$  is resolved.
- E-SEND:** an send expression **send**  $e_1$  **to**  $e_2$  evaluates  $e_1$  to a value  $v_1$  and  $e_2$  to a handle  $h_2$  and then uses the library function *send* to send  $v$  to  $h$ . The value  $v_1$  must be a string.

**E-RECV:** an receive expression `recv e` evaluates  $e$  to a handle  $h$  and then uses the library function `recv` to obtain a promise  $\rho$  that resolves to a message sent to  $h$ . The message must be a string.

**E-SPAWN:** a spawn expression `spawn e1 with e2` evaluates  $e_1$  to a function closure  $v_1$  and  $e_2$  to  $v_1$ 's argument  $v_2$  and then uses the library function `spawn` to update the runtime state with a new thread scheduled to run the function call  $v_1 v_2$  and return a handle  $h$  to that new thread.

**E-SELF:** a self expression `self` uses the library function `self` to obtain the handle of the calling (current) thread.

## Simplified Semantics

As you build your implementation of the semantics in OCaml, there are a few practical considerations worth keeping in mind. First, the `Mwt` module serves as the concurrency library and provides all of the operations needed to implement the asynchronous expressions. Second, it is not necessary to thread the runtime state  $\Delta$  and store  $\sigma$  through the entire evaluation. Instead, you can rely on OCaml's built-in imperative features to do that for you. Hence, the `eval` function has type: `env -> expr -> value`. Generally speaking, you can simply elide the run-time state  $\Delta$  and store  $\sigma$  when mapping the big-step semantics rules to OCaml code.

It may be helpful to work with a simpler relation,  $\langle \mathcal{E}, e \rangle \Downarrow v$ , which can intuitively be read as follows, “under environment  $\mathcal{E}$ , the expression  $e$  evaluates to value  $v$ ,” eliding the side effects on  $\Delta$  and  $\sigma$ . Following is a formal definition of this relation, using streamlined versions of the concurrency library functions that elide  $\Delta$ .

$$\begin{array}{c}

\\
\text{E-SELF} \frac{h = \text{self } \mathcal{E}}{\langle \mathcal{E}, \text{self} \rangle \Downarrow h}
\end{array}$$

## Definitions and Programs

A complete RML program is defined as a non-empty list of definitions:

$$\begin{array}{ll}
\text{prog} \in \text{Prog} & ::= \quad d \quad \text{Single definition} \\
& \mid \quad d \text{ prog} \quad \text{Definition followed by more definitions}
\end{array}$$

A definition is either a let-definition or a let-rec-definition:

$$\begin{array}{ll}
d \in \text{Defn} & ::= \quad \text{let } (p : \tau) = e \quad \text{Let definition} \\
& \mid \quad \text{let rec } (f : \tau_1 \rightarrow \tau_2) = \text{fun } (p : \tau_1) \rightarrow e \quad \text{Let rec definition}
\end{array}$$

The relation  $\langle \mathcal{E}, d \rangle \Downarrow \mathcal{E}'$ , which can be read “under environment  $\mathcal{E}$ , the definition  $d$  emits the updated environment  $\mathcal{E}'$ ”, is given as follows:

$$\begin{array}{c}
\text{E-DLET} \frac{\langle \mathcal{E}, e \rangle \Downarrow v \quad v : p \rightsquigarrow \mathcal{E}'}{\langle \mathcal{E}, \text{let } (p : \tau) = e \rangle \Downarrow \mathcal{E} \circ \mathcal{E}'} \\
\\
\text{E-DLETREC} \frac{\mathcal{E}_f = \mathcal{E}[f \mapsto (|\mathcal{E}_f, p, e|)] \quad \langle \mathcal{E}_f, e \rangle \Downarrow v \quad v : f \rightsquigarrow \mathcal{E}'}{\langle \mathcal{E}, \text{let rec } (f : \tau) = e \rangle \Downarrow \mathcal{E} \circ \mathcal{E}'}
\end{array}$$

Program evaluation simply threads the empty environment through the definitions, accumulating more new mapping each time:

$$\text{E-PROG} \frac{\langle \emptyset, d_1 \rangle \Downarrow \mathcal{E}_1 \quad \dots \quad \langle \mathcal{E}_{n-1}, d_n \rangle \Downarrow \mathcal{E}}{d_1 \ \dots \ d_n \Downarrow \mathcal{E}}$$

## Type System

As discussed in the assignment writeup, the behavior of the interpreter is undefined if the program in question does not pass the type checker. The type system of RML is very similar to that of OCaml, and should not be hard to reason about informally. However, we include the following typing rules for those who wish to reason more carefully about what programs are considered valid in RML. It is not required to read or understand the typing rules, and you may feel free to skip them if you wish.

For the typing judgement, we will need to define the notion of a *typing context*, a partial map from variable names to types. We will use the capital Greek letter  $\Gamma$  for contexts:

$$\Gamma : Var \rightarrow Type$$

We adopt the following notational conventions for describing typing contexts:

- $dom \Gamma$  denotes the domain of  $\Gamma$ , that is the set of variable that it is defined on,
- $\emptyset$  denotes the typing context that is undefined on all variables,
- $\Gamma, x : \tau$  denotes the typing context that maps  $x$  to  $\tau$  and all other  $y \in dom \Gamma$  to  $\Gamma(y)$ .
- $\Gamma_1, \Gamma_2$  denotes the typing context that maps  $x$  in  $dom \Gamma_2$  to  $\Gamma_2(x)$ ,  $x$  in  $dom \Gamma_1$  but not in  $dom \Gamma_2$  to  $\Gamma_1(x)$ , and is otherwise undefined.

First we will give the auxiliary definition for typing patterns, denoted  $p : \tau \rightsquigarrow \Gamma$ . This can be read “pattern  $p$  is of type  $\tau$  and produces typing context  $\Gamma$ ”. In describing these the typing rules for RML, we will use notation similar to what is used to describe the big-step semantics.

$$\begin{array}{c} \overline{-- : \tau \rightsquigarrow \emptyset} \quad \overline{() : \mathbf{unit} \rightsquigarrow \emptyset} \quad \overline{b : \mathbf{bool} \rightsquigarrow \emptyset} \quad \overline{n : \mathbf{int} \rightsquigarrow \emptyset} \\[10pt] \overline{s : \mathbf{string} \rightsquigarrow \emptyset} \quad \overline{x : \tau \rightsquigarrow x : \tau, \emptyset} \quad \overline{[] : \tau \mathbf{list} \rightsquigarrow \emptyset} \\[10pt] \frac{p_1 : \tau_1 \rightsquigarrow \Gamma_1 \quad p_2 : \tau_2 \rightsquigarrow \Gamma_2}{(p_1, p_2) : \tau_1 * \tau_2 \rightsquigarrow \Gamma_1, \Gamma_2} \quad \frac{p_1 : \tau \rightsquigarrow \Gamma_1 \quad p_2 : \tau \mathbf{list} \rightsquigarrow \Gamma_2}{p_1 :: p_2 : \tau \mathbf{list} \rightsquigarrow \Gamma_1, \Gamma_2} \end{array}$$

The typing judgement for expressions will be written  $\Gamma \vdash e : \tau$ , and can be read “ $\Gamma$  shows that  $e$  is of type  $\tau$ ”. Some rules involve type substitutions  $S$ , which are partial maps from type variables to types. We write  $S(\tau)$  for the result of applying substitution  $S$  to  $\tau$ .

$$\begin{array}{c} \overline{\Gamma \vdash () : \mathbf{unit}} \quad \overline{\Gamma \vdash b : \mathbf{bool}} \quad \overline{\Gamma \vdash n : \mathbf{int}} \quad \overline{\Gamma \vdash s : \mathbf{string}} \\[10pt] \frac{\Gamma(x) = \tau}{\Gamma \vdash x : \tau} \quad \frac{\Gamma(x) = \forall(\tau_1 \rightarrow \tau_2)}{\Gamma \vdash x : S(\tau_1) \rightarrow S(\tau_2)} \quad \frac{\Gamma \vdash e_1 : \tau_1 \quad \Gamma \vdash e_2 : \tau_2}{\Gamma \vdash (e_1, e_2) : \tau_1 * \tau_2} \\[10pt] \overline{\Gamma \vdash [] : \tau \mathbf{list}} \quad \frac{\Gamma \vdash e_1 : \tau \quad \Gamma \vdash e_2 : \tau \mathbf{list}}{\Gamma \vdash e_1 :: e_2 : \tau \mathbf{list}} \\[10pt] \frac{p : \tau \rightsquigarrow \Gamma' \quad \Gamma, \Gamma' \vdash e : \tau'}{\Gamma \vdash \mathbf{fun} (p : \tau) \rightarrow e : \tau \rightarrow \tau'} \quad \frac{\Gamma \vdash e_1 : \tau \quad p : \tau \rightsquigarrow \Gamma' \quad \Gamma, \Gamma' \vdash e_2 : \tau'}{\Gamma \vdash \mathbf{let} (p : \tau) = e_1 \mathbf{in} e_2 : \tau'} \\[10pt] \frac{\Gamma \vdash e_1 : \tau \quad \Gamma, x : \forall(\tau_1 \rightarrow \tau_2) \vdash e_2 : \tau' \quad e_1 \text{ is value}}{\Gamma \vdash \mathbf{let} (x : \tau_1 \rightarrow \tau_2) = e_1 \mathbf{in} e_2 : \tau'} \end{array}$$

$$\begin{array}{c}
